

Negative turbulent heat flux feedback

F. Massonnet and J. García-Serrano

Workshop on Feedbacks in Polar Regions

May 17th, 2016

Arctic Sea Ice Extent

(Area of Ocean with at least 15% sea ice)

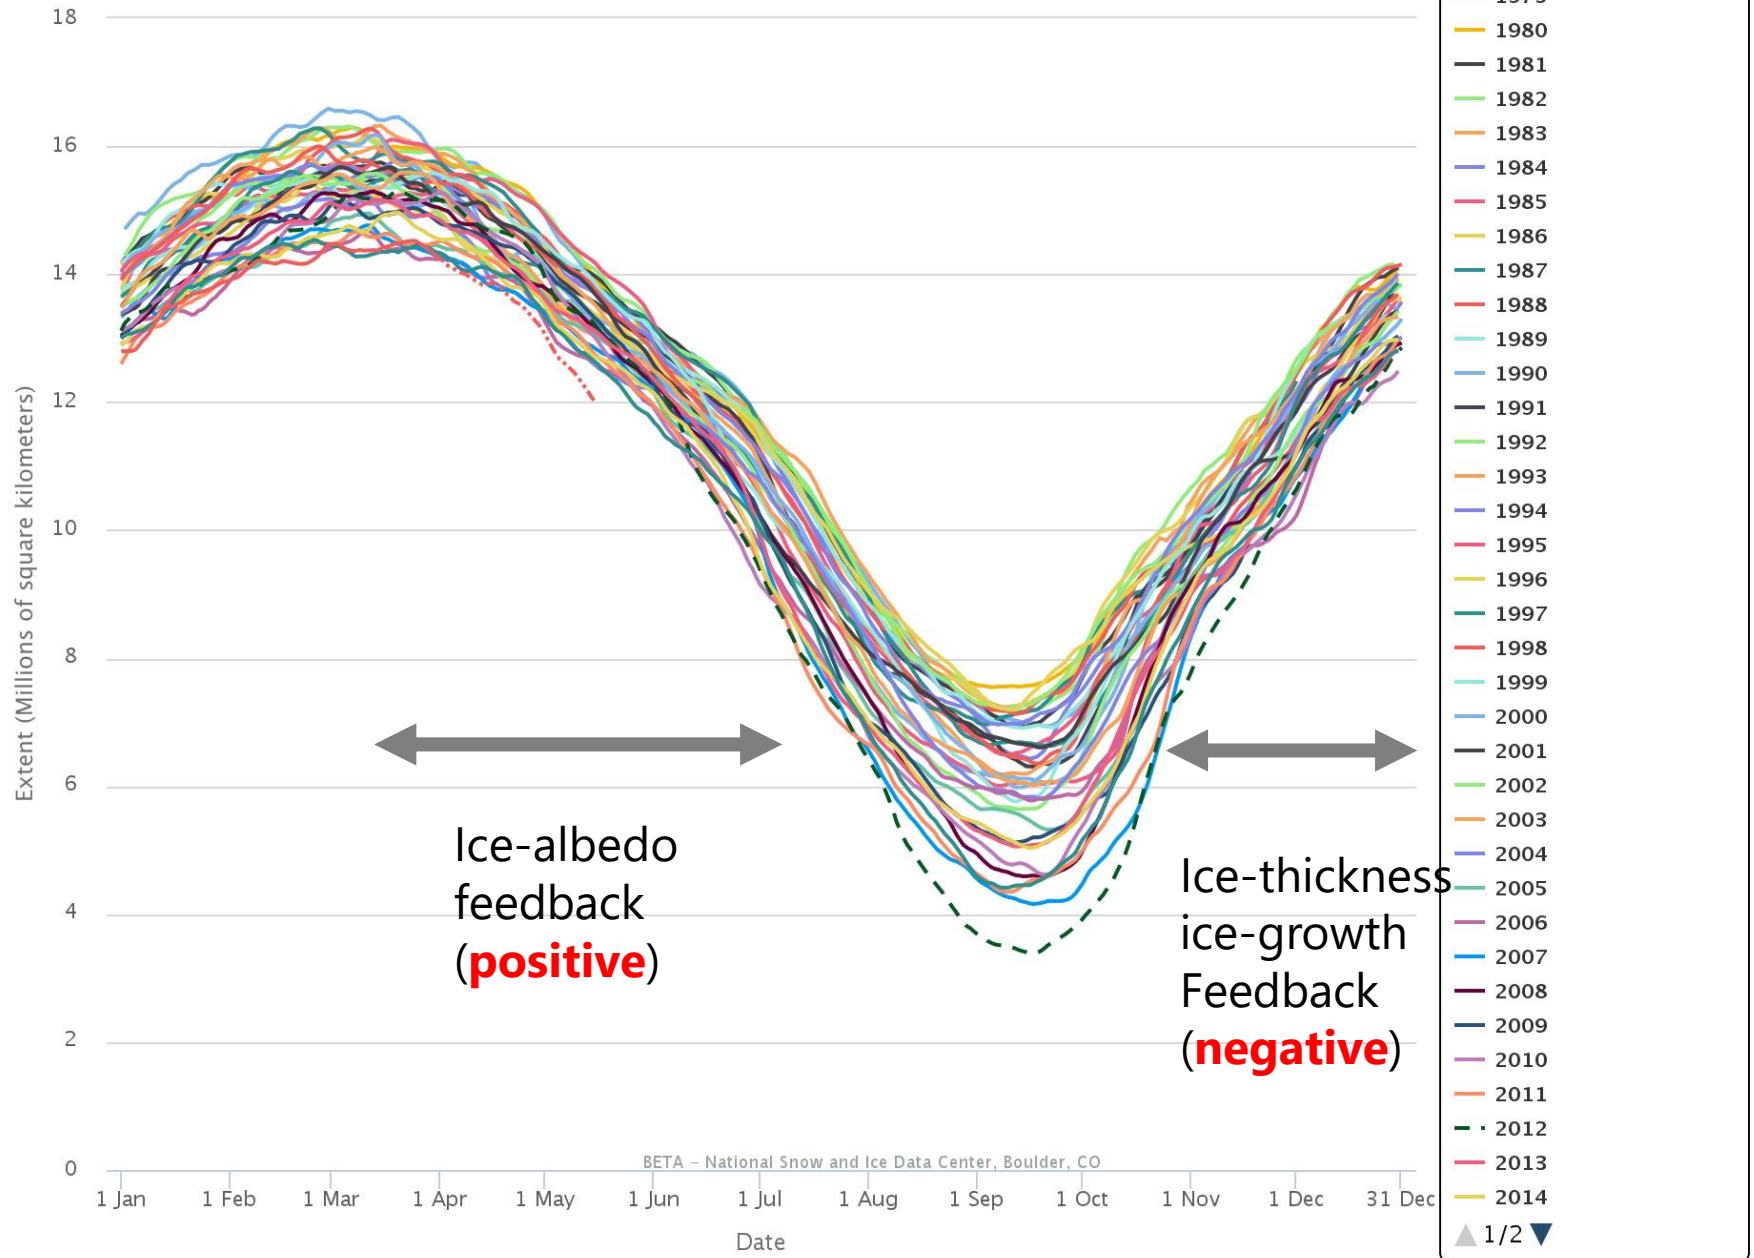

Arctic Sea Ice Extent

(Area of Ocean with at least 15% sea ice)

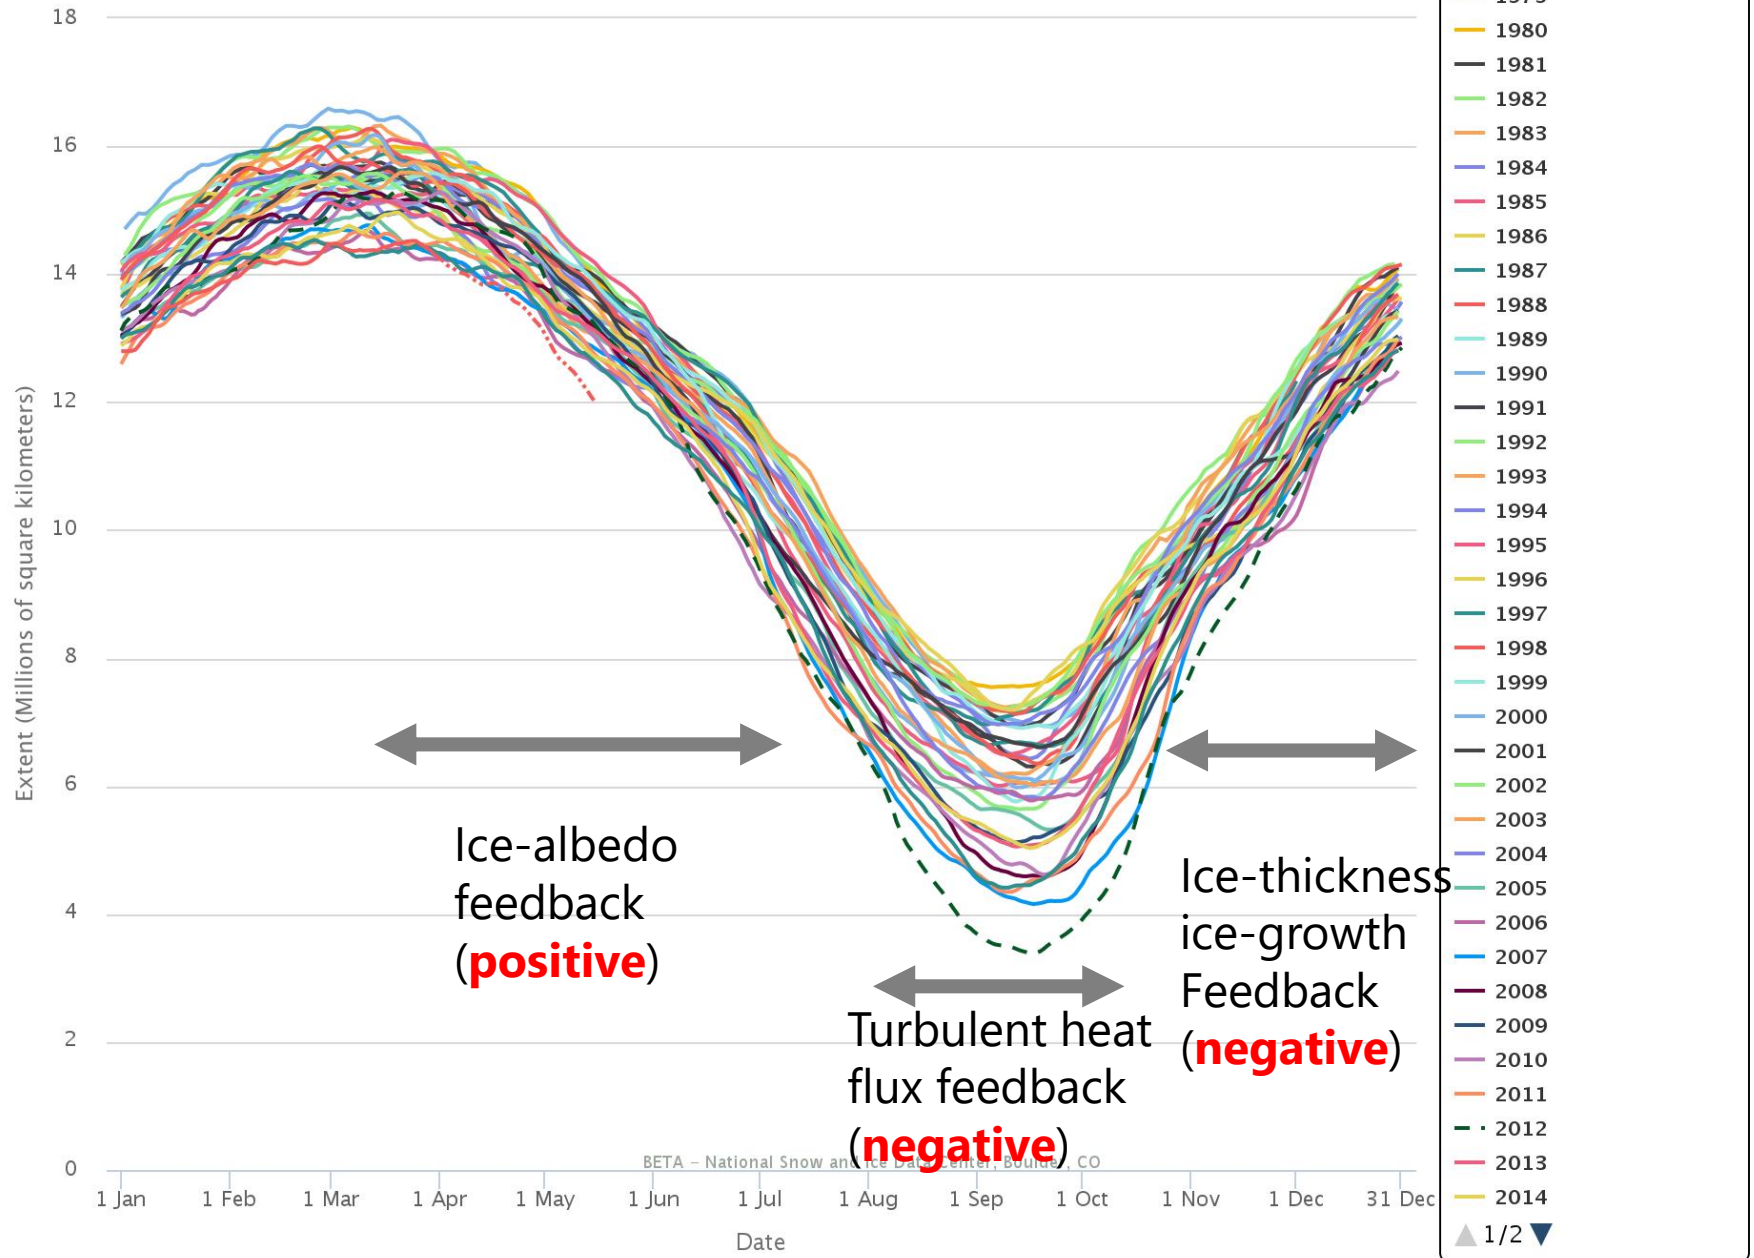

Arctic Sea Ice Extent

(Area of Ocean with at least 15% sea ice)

Arctic Sea Ice Extent

(Area of Ocean with at least 15% sea ice)

Sea ice surface energy balance

Sea ice surface energy balance

Part 1 – F_T in an atmospheric reanalysis

Part 2 – F_T in an ocean—sea ice model

Sea ice surface energy balance

Part 1 – F_T in an atmospheric reanalysis

Part 2 – F_T in an ocean—sea ice model

The F_T -feedback is *negative* and can be characterized by the autocorrelation of the F_T

1979-2015 correlation of August vs September F_T anomalies

Proposed mechanism: sea ice/ocean as a temporary storage of turbulent heat

Normal year

Proposed mechanism: sea ice/ocean as a temporary storage of turbulent heat

Sea ice surface energy balance

Part 1 – F_T in an atmospheric reanalysis

Part 2 – F_T in an ocean—sea ice model

Sea ice surface energy balance

Part 1 – F_T in an atmospheric reanalysis

Part 2 – F_T in an ocean—sea ice model

version 3.6 (~CMIP6)

forced by

DRAKKAR

ORCA1 grid (~50
km at the poles)

First order diagnostics for that model: total September sea ice volume and extent

First order diagnostics for that model: sea ice thickness

Ref. period:
1986-2005

1986-2005 March Arctic sea ice thickness

1986-2005 September Arctic sea ice thickness

1986-2005 March Antarctic sea ice thickness

1986-2005 September Antarctic sea ice thickness

Back to turbulent heat
flux diagnostics!

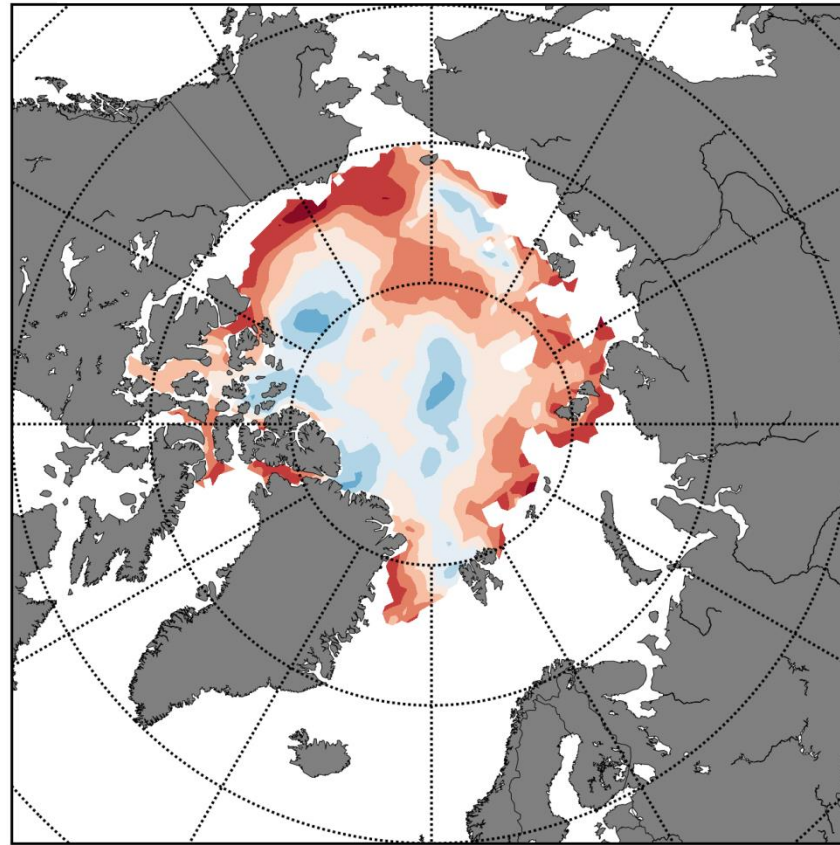

Autocorrelation of Beaufort Sea turbulent flux anomalies

This negative correlation matches the one identified in ERA-Interim, although it happens earlier in the model. And in fact the model is known to reach its minimum about a month earlier than in reality

The model has longer persistence than the reanalysis...

July to **August** correlation of F_T

Ref: 1979-1999
(simulation is ongoing
to output that
particular diagnostic!)

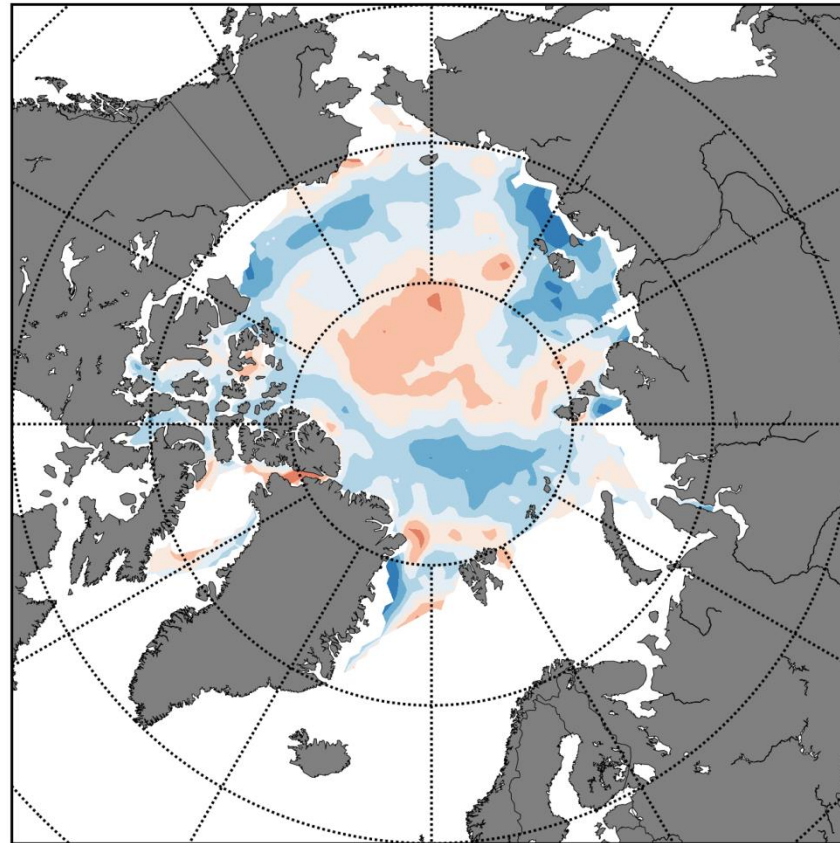

The model has longer
persistence than the reanalysis...

July to **September** correlation of F_T

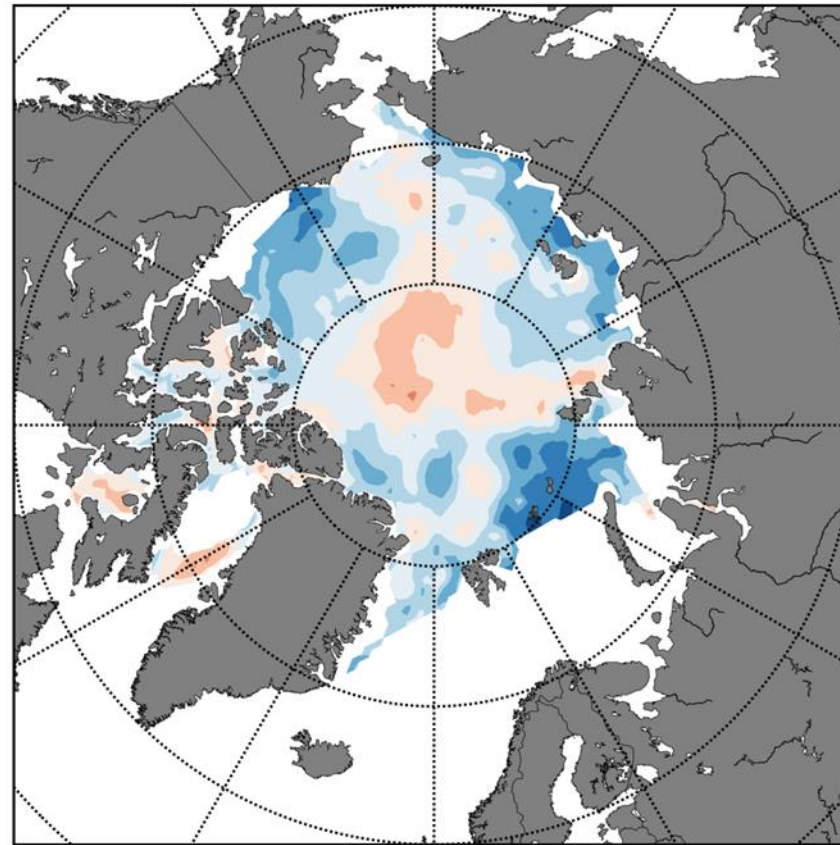

... but eventually exhibits
the same feedback

July to **October** correlation of F_T

... but eventually exhibits
the same feedback

July to **November** correlation of F_T

Sea ice surface energy balance

Part 1 – F_T in an atmospheric reanalysis

Part 2 – F_T in an ocean—sea ice model

Conclusions & perspectives

- The Turbulent Heat Flux Feedback is **negative**

Over a year, it competes with the *positive* ice-albedo feedback

- It is a **coupled** atmosphere-ice feedback

The (slow) ice damps anomalies from the (fast) atmosphere

- The feedback is straightforward to **characterize**

It expresses itself as a negative autocorrelation in F_T heat flux

- It is seen in a **reanalysis** and an ocean-sea ice **model**

Is it also present in coupled models?

- Also seen in a **low-order sea ice model?**

A feedback is robust if it is independent of model complexity

Thank you

F. Massonnet and J. García-Serrano
